

## O<sub>2</sub> optodes

Data acquisition, state of the art of sensor knowledge, implementation and recommendations

Best practices:  
 (1) Know your sensor!  
 (2) Get to know your sensor in the lab first under controlled conditions.

**Henry Bittig**  
**IOW, Baltic Sea Research Institute Warnemünde**

Workshop on Interoperability Technologies and Best Practices in Environmental Monitoring - Brest, 10-12 October 2018

Henry Bittig, Brest / France, 12. Oct. 2018

## O<sub>2</sub> sensors

Variety of dimensions:  
 self-logging – online, cabled – autonomous, fixed – profiling, electrochemical – luminescence quenching

Variety of implications:  
 endurance (power, fouling), needed stability, time response, characterization of the probe

Variety of implementations

Henry Bittig, Brest / France, 12. Oct. 2018

## O<sub>2</sub> sensors

Variety of dimensions:  
 self-logging – online, cabled – autonomous, fixed – profiling, electrochemical – **luminescence quenching**

Variety of implications:  
 endurance (power, fouling), needed stability, time response, **characterization of the probe**

Variety of implementations

Henry Bittig, Brest / France, 12. Oct. 2018

## How do O<sub>2</sub> optodes work?

Dynamic luminescence quenching by O<sub>2</sub>  
 = presence / absence of O<sub>2</sub> modifies luminescence lifetime of a chemical

**ALL O<sub>2</sub> optodes sense the seawater O<sub>2</sub> partial pressure, pO<sub>2</sub>, NOT the seawater O<sub>2</sub> concentration. No matter what they claim!**  
 It's in their sensing principle.

Henry Bittig, Brest / France, 12. Oct. 2018

## How do O<sub>2</sub> optodes work? – pO<sub>2</sub> probes

Dynamic luminescence quenching by O<sub>2</sub>  
 All textbooks say: Quenching ~ O<sub>2</sub> concentration, i.e., #O<sub>2</sub> per vol. ?  
 Right! But O<sub>2</sub> concentration around the luminescent chemical.  
 Is that in Seawater?

Henry Bittig, Brest / France, 12. Oct. 2018

## How do O<sub>2</sub> optodes work? – pO<sub>2</sub> probes

Dynamic luminescence quenching by O<sub>2</sub>  
 All textbooks say: Quenching ~ O<sub>2</sub> concentration, i.e., #O<sub>2</sub> per vol. ?  
 Right! But O<sub>2</sub> concentration around the luminescent chemical.  
 Is that in Seawater?

No. It's immobilized. (In a sensing foil / membrane / coating / polymer)

For the luminescent chemical to sense the seawater's O<sub>2</sub>, O<sub>2</sub> molecules have to exchange with foil / membrane / coating / polymer until there is an equilibrium.  
 → Equal partial pressures!

→ What the luminescent chemical 'sees' is the membrane O<sub>2</sub> concentration c(O<sub>2</sub>)<sup>M</sup> is the seawater's partial pressure pO<sub>2</sub>!

Henry Bitig, Brest / France, 12. Oct. 2018

## O<sub>2</sub> optodes – pO<sub>2</sub> probes

Who cares?

(1) O<sub>2</sub> conc. / pO<sub>2</sub> / O<sub>2</sub> saturation are (distinctly) different sides, albeit of the same thing.

But their relation is modified by

- Temperature T  $T_{\text{corr}} = 44.6596 \cdot \exp(A_0 + A_1 \cdot T + A_2 \cdot T^2 + A_3 \cdot T^3 + A_4 \cdot T^4 + A_5 \cdot T^5)$
- Salinity S  $S_{\text{corr}} = \frac{1013.25 - p(\text{hPa})}{1013.25 - p(\text{hPa})}$   $S_{\text{corr}} = \exp(S \cdot (B_0 + B_1 \cdot T + B_2 \cdot T^2 + B_3 \cdot T^3) + C_0 \cdot S^2)$
- Hydrostatic pressure P  $\exp\left(\frac{V_m \cdot P}{R \cdot T}\right)$
- Atmospheric pressure p<sub>air</sub>  $S_a = \frac{p(\text{hPa})}{1013.25 - p(\text{hPa})}$

Not all conversions impacted by all impact factors.

\*T<sub>corr</sub> and S<sub>corr</sub> from Garcia and Gordon (1992), Benson and Krause refit P from Enns et al. (1965)

Henry Bitig, Brest / France, 12. Oct. 2018

## O<sub>2</sub> conversions – not a stumbling block!

SCOR WG 142: Recommendations on O<sub>2</sub> quantity conversions (incl. Matlab functions) → google or DOI:10.1315/45915

```

function pO2=O2toPO2(O2conc,T,S,P)
%Function pO2=O2toPO2(O2conc,comp,al,press)
%
% convert molar oxygen concentration to oxygen partial pressure
%
% inputs:
% O2conc - oxygen concentration in umol L-1
% T - temperature in °C
% S - salinity (PSU=0)
% P - hydrostatic pressure in dbar (default: 0 dbar)
%
% output:
% pO2 - oxygen partial pressure in dbar
%
% according to recommendations by SCOR WG 142 "Quality Control Procedures
% for Oxygen and Other Biogeochemical Sensors on Floats and Gliders"
%
% Henry Bitig
% Laboratoire d'océanographie de Villefranche-sur-Mer, France
% h.bitig@univ-ler.fr
%
% 2010-10-20
%
% set input default
if nargin, P = 0; end
%
% kO2 = 0.20980 % mole fraction of O2 in dry air (Lueckeap 1951)
% pO2sat = 0.21 * exp(10.4184 - 1485.86/T + 14.7533 * ln(T) - 0.000148 * (T-10)^4); % saturated water vapor in dbar
% kO2L = log(100*(1-T)/(1+T)); % scaled temperature for use in Tcorr and Scorr
% Tcorr = exp(10.4184 - 1485.86/T + 14.7533 * ln(T) - 0.000148 * (T-10)^4); % temperature
% correction part from Garcia and Gordon (1992), Benson and Krause (1981) refit MLSTP L-1; and conversion from MLSTP L-1 to umol L-1
% Scorr = exp(S * (B0 + B1 * T + B2 * T^2 + B3 * T^3) + C0 * S^2); % salinity correction part
% from Garcia and Gordon (1992), Benson and Krause (1981) refit MLSTP L-1
% Vm = 0.3114 % molar volume of O2 in dbar refit: Enns et al. 1965
% R = 8.314 % universal gas constant in J mol-1 K-1
%
% pO2=O2conc.*kO2.*exp(10.4184 - 1485.86/T + 14.7533 * ln(T) - 0.000148 * (T-10)^4) ./ (Tcorr .* Scorr .* exp(Vm .* P ./ (R .* T)));

```

Henry Bitig, Brest / France, 12. Oct. 2018

## (2) To get the characterization right.

What characterization?

- (Equilibrium) response to O<sub>2</sub> %, to T, to S and to P
- Is there a delay τ for these responses? (e.g., O<sub>2</sub> time response, pressure hysteresis)
- Do these responses change over time Δt? If yes, in which way?

Best practice:

If you want to put your sensor in a given environment (O<sub>2</sub>, T, S, P, maybe τ), know the behaviour of your probe beforehand (or know how to check).

At best from lab experiments, where you can vary environment one variable at a time. Tedious, but rewarding!

Henry Bitig, Brest / France, 12. Oct. 2018

## O<sub>2</sub> and Temperature response

O<sub>2</sub> and T response well-recognized; typically done

- 2D matrix of varying O<sub>2</sub> and T while tracking sensor response Φ
- Subsequent fit of mathematical model to data  $pO_2 = F(T, \Phi)$

Non-linear Stern-Volmer (& non-linear O<sub>2</sub>) behaviour

Henry Bitig, Brest / France, 12. Oct. 2018

## Salinity response

O<sub>2</sub> optodes do not have a salinity response, if the foil / membrane / coating / polymer is inert / impermeable to salt. (Typically the case.)

Wait: What about all these "Salinity corrections" à la S<sub>corr</sub>? I see elsewhere??

Only for optodes that claim to measure O<sub>2</sub> concentration, right?!

Example: 200 μmol/L at 25 °C and	S=0	S=20	S=35
pO <sub>2</sub> is	159 hPa	179 hPa (+12 %)	195 hPa (+22 %)
"c(O <sub>2</sub> )" optode gives	200 μmol/L	224 μmol/L (+12 %)	244 μmol/L (+22 %)
"pO <sub>2</sub> " optode gives	159 hPa	179 hPa (+12 %)	195 hPa (+22 %)

- O<sub>2</sub> optodes see the ambient pO<sub>2</sub>, see the ambient pO<sub>2</sub>, and see the ambient pO<sub>2</sub>, no matter whether at S=0, S=20, or S=35.
- "Salinity correction" comes only from pO<sub>2</sub> c(O<sub>2</sub>) (fresh/salty) conversions needed if assumed to 'sense' seawater O<sub>2</sub> concentration. → Avoid in the first place, no need to salinity-correct afterwards.
- Hard to spot on 'xx μmol/L' whether salinity-corrected or not → Errors

Henry Bitig, Brest / France, 12. Oct. 2018

## Hydrostatic pressure response

Why does P affect pO<sub>2</sub> sensing?

From fundamental thermodynamics:  $\frac{pO_2(P)}{pO_2(0 \text{ dbar})} = \exp\left(\frac{V_m \cdot P}{R \cdot T_{\text{abs}}}\right)$

V<sub>m</sub> – partial molar volume

In words: "higher outgassing tendency"; pO<sub>2</sub> increases & O<sub>2</sub> solubility decreases under pressure due to solute-solvent interactions

V<sub>m</sub> of O<sub>2</sub> in silicone: -42 mL/mol → -+20 % / 1000 dbar

V<sub>m</sub> of O<sub>2</sub> in water: 31.7 mL/mol → +15 % / 1000 dbar

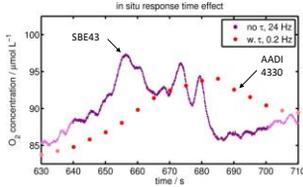

ratio ('seen' by luminescence quenching due to re-equilibration between foil / water): -4-5 % / 1000 dbar

## Response delays $\tau$ ?

O<sub>2</sub> molecules need time to diffuse in/out of sensing foil. Causes "lag" and "smearing". Reasonably-well understood → Corrections possible.

O<sub>2</sub> time response is faster:

- with faster flow in front of foil (liquid boundary layer)
- at higher T (diffusivity & solubility T-dependence)

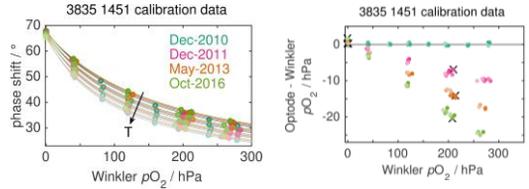

No (rare?) observations of a P time response (pressure hysteresis).

## Response changes (long-term)?

All of the above, but in repeated intervals (after / during deployment)! Figure out what's happening and use knowledge.

Example: O<sub>2</sub> – T response evolution of PreSens foils

Gets at character of drift / stability. Can be different for different implementations (e.g., PyroScience, JFE Advantech, ...)!

## Take Home

(1) Know your sensor!

E.g. Sensing principle renders O<sub>2</sub> optodes seawater pO<sub>2</sub>-sensitive. And not depending on salinity.

(2) If you want to put your sensor in a given environment, know the behaviour of your probe beforehand (or know how to check).

(2b) Get to know your sensor in the lab first under controlled conditions, where you can vary environment one variable at a time. Tedious, but rewarding!

(3) O<sub>2</sub> conversions no stumbling block: SCOR WG 142 recommendations.

More details on O<sub>2</sub> optodes: [Frontiers paper](#) and references therein.
